## List of Figures

1	Aerial image of Port San Luis and San Luis Obispo Bay. The view is to the northwest, with Harford Pier the furthest away and the Avila Beach community in the foreground. . . . .	19
2	Aerial view of the Diablo Canyon Power Plant, which is located 10 kilometers northwest of Port San Luis. . . . .	20
3	Perspective views of the Port San Luis 1/3-arc-sec DEM from the southeast (Courtesy of NGDC). . . . .	21
4	Satellite image of the Port San Luis area and the surrounding communities. .	22
5	Photo of the Harford Pier at Port San Luis. The Port San Luis tide gauge is located on this pier, and the telemetry station is housed in the large grey building in the center of photograph. The weather package can be seen mounted on the building's roof. . . . .	23
6	Bathymetry for the reference inundation model grids. The A grid is shown in the top left panel, the B grid in the top right panel, and the C grid in the bottom panel. The topography of the C grid is shown using contours with 10-m intervals from 0 to 40m and then 40-m intervals for higher values. The red boxes in the A and B grids show the boundaries of the nested B and C grids, respectively. The red star shows the location of the Port San Luis tide gauge. . . . .	24
7	Bathymetry for the forecast inundation model grids. The A grid is shown in the top left panel, the B grid in the top right panel, and the C grid in the bottom panel. The topography of the C grid is shown using contours with 10-m intervals from 0 to 40 m and then 40-m intervals for higher values. The red boxes in the A and B grids show the boundaries of the nested B and C grids, respectively. The red star shows the location of the Port San Luis tide gauge. . . . .	25
8	Map of the Pacific Ocean Basin showing the locations and magnitudes of the twelve historical events used to test and validate the Port San Luis model. Relative earthquake magnitude is shown by the varying sizes and colors of the filled circles. The largest magnitude earthquake used in model validation is the 1960 Chile Mw 9.5 earthquake. The star denotes Port San Luis's location.	26
9	Model results for the 1946 Unimak Mw 8.5 event. The upper two panels show the maximum water surface elevations predicted by the forecast and reference models, respectively. The lower panel shows the time series of wave amplitudes at the Port San Luis tide gauge location as predicted by the forecast (red) and reference models (green), respectively. . . . .	27
10	Model results for the 1960 Chile Mw 8.5 event. The upper two panels show the maximum water surface elevations predicted by the forecast and reference models, respectively. The lower panel shows the time series of wave amplitudes at the Port San Luis tide gauge location as predicted by the forecast (red) and reference models (green), respectively. . . . .	28

11	Model results for the 1964 Alaska Mw 9.2 event. The upper two panels show the maximum water surface elevations predicted by the forecast and reference models, respectively. The lower panel shows the time series of wave amplitudes at the Port San Luis tide gauge location as predicted by the forecast (red) and reference models (green), respectively. . . . .	29
12	Model results for the 1994 Kuril Mw 8.3 event. The upper two panels show the maximum water surface elevations predicted by the forecast and reference models, respectively. The lower panel shows the time series of wave amplitudes at the Port San Luis tide gauge location as predicted by the forecast (red) and reference models (green), respectively. . . . .	30
13	Model results for the 1996 Andreanof Mw 7.9 event. The upper two panels show the maximum water surface elevations predicted by the forecast and reference models, respectively. The lower panel shows the time series of wave amplitudes at the Port San Luis tide gauge location as predicted by the forecast (red) and reference models (green), respectively. . . . .	31
14	Model results for the 2003 Rat Island Mw 7.7 event. The upper two panels show the maximum water surface elevations predicted by the forecast and reference models, respectively. The lower panel shows the time series of wave amplitudes at the Port San Luis tide gauge location as predicted by the forecast (red) and reference models (green), respectively. . . . .	32
15	Model results for the 2006 Tonga Mw 8.0 event. The upper two panels show the maximum water surface elevations predicted by the forecast and reference models, respectively. The lower panel shows the time series of wave amplitudes at the Port San Luis tide gauge location as predicted by the forecast (red) and reference models (green), respectively. . . . .	33
16	Model results for the 2006 Kuril Mw 8.3 event. The upper two panels show the maximum water surface elevations predicted by the forecast and reference models, respectively. The lower panel shows the time series of wave amplitudes at the Port San Luis tide gauge location as predicted by the forecast (red) and reference models (green), respectively. . . . .	34
17	Model results for the 2007 Kuril Mw 8.1 event. The upper two panels show the maximum water surface elevations predicted by the forecast and reference models, respectively. The lower panel shows the time series of wave amplitudes at the Port San Luis tide gauge location as predicted by the forecast (red) and reference models (green), respectively. . . . .	35
18	Model results for the 2007 Solomon Mw 8.1 event. The upper two panels show the maximum water surface elevations predicted by the forecast and reference models, respectively. The lower panel shows the time series of wave amplitudes at the Port San Luis tide gauge location as predicted by the forecast (red) and reference models (green), respectively. . . . .	36
19	Model results for the 2009 Samoa Mw 8.0 event. The upper two panels show the maximum water surface elevations predicted by the forecast and reference models, respectively. The lower panel shows the time series of wave amplitudes at the Port San Luis tide gauge location as predicted by the forecast (red) and reference models (green), respectively. . . . .	37

20	Model results for the 2010 Chile Mw 8.8 event. The upper two panels show the maximum water surface elevations predicted by the forecast and reference models, respectively. The lower panel shows the time series of wave amplitudes at the Port San Luis tide gauge location as predicted by the forecast (red) and reference models (green), respectively. . . . .	38
21	Model results for the 2011 Tohoku Mw 9.0 event. The upper two panels show the maximum water surface elevations predicted by the forecast and reference models, respectively. The lower panel shows the time series of wave amplitudes at the Port San Luis tide gauge location as predicted by the forecast (red) and reference models (green), respectively. . . . .	39
22	Map of the Pacific Ocean Basin showing the locations of the 19 simulated Mw 9.3 events (red circles) and the medium and micro events used to test and validate the Port San Luis model. The solid star denotes the location of Port San Luis. . . . .	40
23	Results from the forecast model for the KISZ 1-10 synthetic event. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	41
24	Results from the forecast model for the KISZ 22-31 synthetic event. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	42
25	Results from the forecast model for the KISZ 32-41 synthetic event. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	43
26	Results from the forecast model for the KISZ 56-65 synthetic event. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	44
27	Results from the forecast model for the ACSZ 6-15 synthetic event. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	45
28	Results from the forecast model for the ACSZ 16-25 synthetic event. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	46
29	Results from the forecast model for the ACSZ 22-31 synthetic event. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	47

30	Results from the forecast model for the ACSZ 50-59 synthetic event. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	48
31	Results from the forecast model for the ACSZ 56-65 synthetic event. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	49
32	Results from the forecast model for the CSSZ 1-10 synthetic event. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	50
33	Results from the forecast model for the CSSZ 37-46 synthetic event. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	51
34	Results from the forecast model for the CSSZ 89-98 synthetic event. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	52
35	Results from the forecast model for the CSSZ 102-111 synthetic event. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	53
36	Results from the forecast model for the NTSZ 30-39 synthetic event. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	54
37	Results from the forecast model for the NVSZ 28-37 synthetic event. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	55
38	Results from the forecast model for the MOSZ 1-10 synthetic event. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	56
39	Results from the forecast model for the NGSZ 3-12 synthetic event. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	57
40	Results from the forecast model for the EPSZ 6-15 synthetic event. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	58

41	Results from the forecast model for RNSZ 12-21 synthetic event. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	59
42	Results from the forecast model for the medium synthetic event, with a $1.0 \times \text{NTSZ}$ B36 source. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	60
43	Results from the forecast model for the micro synthetic event, with a $0.05 \times \text{ACSZ}$ B6 source. The upper panel shows the map of predicted maximum wave height in the Port San Luis C grid, and the lower panel shows the time series of wave amplitude at the tide gauge location. . . . .	61

**Abstract** In support of the National Oceanic and Atmospheric Administration’s tsunami forecast system, we developed a tsunami forecast model for Port San Luis, California, and neighboring communities on San Luis Obispo Bay. The Port San Luis tsunami forecast model employs the Method of Splitting Tsunami numerical code, running in three telescoped nested grids with successively finer resolutions. The innermost grid covers the population and economic center of the community at a resolution of 62 m. A higher-resolution reference model, without limitation on runtime, has also been developed to provide comparison for the forecast model. The models have been tested with 13 historical tsunamis. Good agreement was observed between the forecast and reference models, as well as with available tide gauge data. The forecast model was also tested for 19 synthetic mega-tsunami events forced by Mw 9.3 earthquakes. Responses to a number of these events are quite severe at Port San Luis, suggesting that there is a large potential risk resulting from strong earthquakes around the Pacific Basin. The forecast model has maintained numerical stability in all these tests. To complete a simulation of 4 hr of wave processes, the forecast model needs approximately 11.2 min of CPU time, which is considered fast enough for real-time forecast computations. All the observations in this report suggest that the Port San Luis forecast model is ready to be integrated into the tsunami forecast system for operational deployment.

## 1 Background and Objectives

The National Oceanic and Atmospheric Administration (NOAA) Center for Tsunami Research (NCTR) at the NOAA Pacific Marine Environmental Laboratory (PMEL) has developed a tsunami forecasting capability for operational use by NOAA's two tsunami warning centers located in Hawaii and Alaska (Titov et al., 2005). The system is designed to efficiently, accurately, and quickly provide basin-wide warning of approaching tsunami waves. The system, termed Short-term Inundation Forecast of Tsunamis (SIFT), combines real-time tsunami event data with numerical models to produce estimates of tsunami wave arrival times and amplitudes at coastal communities of interest. SIFT integrates several key components: deep-ocean observations of tsunamis in real time, a basin-wide precomputed propagation database of water surface elevations and flow velocities based on potential seismic unit sources, an inversion algorithm to refine the tsunami source based on deep-ocean observations during an event, and high-resolution tsunami forecast models.

Port San Luis is located on the southern California coast, approximately 330 km south of San Francisco and 260 km to the northwest of Los Angeles. The port originally served as the shipping and transportation center for the city of San Luis Obispo, which is 15 km inland. Although there is still a working commercial fishing pier, and the inland areas have extensive orchards, tourism is now the main industry of this region. Port operations are centered on Harford Pier, the westernmost of the three long piers in the bay. The Harford Pier serves both commercial and recreational fishing users and serves as a focal point for tourism, hosting two restaurants and an event space. The two other piers on the bay, i.e., the Cal Poly Marine Education and Research Pier and the Avila Pier, are used for marine science research and tourism. Figure 1 shows an aerial view of Port San Luis looking from the southeast. In this figure, Harford Pier is the furthest away, with the Cal Poly Pier in the middle, and Avila Pier and the town center of Avila Beach in the foreground.

We refer to this model as the Port San Luis model in order to coincide with the name of the tide gauge. This area is more commonly known as Avila Beach. Avila Beach is a small town located on the northern edge of San Luis Obispo Bay, with a population of 1,627 (US Census Bureau, 2010). Further along the coast to the southeast are Pismo Beach, population 7,665 (US Census Bureau, 2010), and Grover Beach, population 13,156 (US Census Bureau, 2010). The Port San Luis area is also home to the Diablo Canyon Nuclear power plant, which has been in operation since 1985. The plant is 10 km to the northwest of the San Luis Obispo Bay on the coast, and intakes ocean water for cooling. An aerial photo of the plant is shown in Figure 2. To orient the viewer, the headland seen to the south in the photo is Point San Luis. Approximately 1,200 employees of the plant commute through the Port San Luis area on an access road originating just west of Avila Beach.

Historically, the Port San Luis area has been affected by most major tsunamis in the Pacific Ocean. Most of them were due to distant earthquake sources. Some small scale local events have also been observed in this area. In this study, we develop a tsunami forecast model for the Port San Luis area. This model is designed to be integrated into the SIFT system to further expand its forecast capability.

## 2 Forecast Methodology

The main objective of a forecast model is to provide a quick and accurate estimate of wave arrival time, wave height, and inundation at a community of interest in the minutes following the generation of a tsunami. The basis of a tsunami forecast model is a numerical model, which simulates the wave processes in high-resolution computational grids in real time. All these models are designed and tested to perform under stringent time constraints, given that time is generally the single limiting factor in saving lives and property.

Numerical computations in SIFT are performed with the Method of Splitting Tsunami (MOST), a suite of numerical codes capable of simulating three processes of tsunami evolution: generation due to earthquake, transoceanic propagation, and inundation of dry land. MOST has been extensively tested against a number of laboratory experiments and benchmarks (Synolakis et al., 2008), and was successfully used for the simulations of many historical tsunami events. Titov and González (1997) describe the technical aspects of forecast model development, testing, and robustness, and Tang et al. (2009) provide detailed forecast methodology.

A basin-wide tsunami propagation database has been developed to expedite forecasts (Gica et al., 2008). The propagation database includes precomputed water surface elevations and flow velocities for unit sources covering worldwide subduction zones. As tsunami waves propagate across the ocean and successively reaches tsunameter observation sites, recorded sea level is ingested into the tsunami forecast application in near real time and incorporated into an inversion algorithm to produce an improved estimate of the tsunami source. A linear combination of the precomputed database is then performed based on this tsunami source to produce boundary conditions of water surface elevation and flow velocities to force the forecast model computation.

Propagation and coastal inundation of tsunamis in a tsunami forecast model are simulated in real time. The computations are performed in a set of three nested grids, referred to as A, B, and C grids, each of which becomes successively finer in resolution as they telescope into the population and economic center of the community of interest. The offshore area is covered by the largest A grid at the lowest resolution, and the near-shore details are resolved within the finest C grid to the point that tide gauge observations recorded during historical tsunamis are resolved within expected accuracy limits. Accurate forecasting of the tsunami impact on a coastal community largely relies on the accuracies of bathymetry and topography and the numerical computation. The high resolution necessary for modeling accuracy poses a challenge in the runtime requirement for real-time forecasts. A balance between accuracy and efficiency is sought in the development of a tsunami forecast model. Previous and present development of forecast models in the Pacific (Titov et al., 2005; Titov, 2009; Tang et al., 2008; Wei et al., 2008) have validated the accuracy and efficiency of each forecast model currently implemented in SIFT. Models are tested with historical events and with new events when the opportunity arises and are also used for scientific research.

## 3 Model Development

Computational grids in a tsunami forecast model are developed based on the high-resolution digital elevation models (DEMs) constructed by the National Geophysical Data Center

(NGDC) and NCTR using best available bathymetric, topographic, and shoreline data. All DEMs are referenced to Mean High Water in the vertical dimension and to the World Geodetic system 1984 horizontal datum in the horizontal dimension (<http://ngdc.noaa.gov/mgg/inundation/tsunami/inundation.html>). We consider these DEMs to be an adequate representation of local topography and bathymetry. As new DEMs become available, the forecast models will be updated and report updates will be posted at “[http://nctr.pmel.noaa.gov/forecast\\_reports/](http://nctr.pmel.noaa.gov/forecast_reports/)”. From these DEMs, a set of three high-resolution, “reference” elevation grids are constructed for a high-resolution reference model. From this reference model, an “optimized” model is constructed by downsampling the reference model grids to reduce the resolution and shrink the overall grid dimensions. This procedure is aimed to limit the runtime of the forecast model within 10 min for a 4-hr simulation. The operationally developed model is referred to as the “optimized tsunami forecast model” or “forecast model” for brevity.

The grids in the Port San Luis reference and forecast models were derived from the Pacific basin-wide 30-arc-sec DEM developed at NCTR, and the 1/3-arc-second DEM provided by NGDC (Friday et al., 2011). A perspective view of the latter DEM is shown in Figure 3.

### 3.1 Forecast area

The forecast and reference models developed here are centered on Port San Luis and San Luis Obispo Bay. The bay, as shown in the satellite image in Figure 4, is a half-moon bay formed by the coast to the east and the Point San Luis headland to the west. It is open to the Pacific Ocean to the southwest. A breakwater, completed in 1913, extends from Point San Luis (incorporating the small Whaler’s Island) to protect the Harford Pier and boat moorings in the bay from incoming westerly storm waves. The town of Avila Beach is located on the northern edge of the bay at the mouth of the San Luis Obispo Creek. The town sits just behind the low flat beach, with the majority of structures between the beach and the creek. Further to the southeast are the towns of Pismo Beach and Grover Beach. There are many houses built right on the waterfront in these communities, but the majority are built on bluffs significantly above sea level. A notable exception to this is Pismo Beach, where the coast again has a wide flat beach. There is also low topography along the Pismo Creek waterway.

On a larger scale, Port San Luis and San Luis Obispo Bay are located about 80 km north of Point Conception and the Southern California Bight, as well as the heavily populated areas found there. To the north of Port San Luis Bay, the rugged California coast trends to the northwest, and is mostly empty of population centers until the Monterey Bay area 200 km away. Offshore of Port San Luis, the continental shelf is fairly wide with a width of up to nearly 100 km. There is evidence (Petersen et al., 2008) of a complex field of local tectonic faults offshore, including the Hosgri and Santa Lucia fault zones. The 1927 Lompoc earthquake likely occurred in this fault zone and led to small tsunami waves reported at Pismo Beach and Port San Luis. This historical evidence stresses the importance of developing a tsunami forecast model for this area.

### 3.2 Historical events

The majority of historical tsunamis that have been observed in the San Luis Obispo Bay area have been from distant earthquake sources. The largest responses at Port San Luis were due to the 1946 Unimak Mw 8.1 earthquake (1.3 m at the Avila Beach tide gauge), the 1964 Alaska Mw 9.2 (1.73 m at Avila Beach), and the 2011 Tohoku, Japan Mw 9.0 earthquake (2.0 m at the Port San Luis tide gauge). These events will be discussed further and employed for model validation in Section 4.1.

There are two tsunamis forced by local events that had significant impact in this area. On 22 November 1878, a set of large waves destroyed the People's Wharf at Avila Beach. It also damaged a pier at Point Sal, 30 km to the south, and drowned a man working on that pier. There was no earthquake observed. This tsunami is believed to have been caused by a local submarine landslide (Lander et al., 1993). Another local tsunami, caused by the 1927 Lompoc Mw 7.5 earthquake offshore of Point Arguello (65 km south of Port San Luis), forced a 5-ft (1.5-m) wave at Port San Luis and a 6-ft (1.8-m) wave at Pismo Beach.

### 3.3 Tide gauge data

The National Ocean Service tide gauge is currently located on the Harford Pier ( $35.16888^{\circ}\text{N}$ ,  $120.75378^{\circ}\text{W}$ ), in the northwest corner of San Luis Obispo Bay. The tide station telemetry equipment is located in the warehouse building at the end of the pier (Figure 5). The water depth at the tide gauge location is 7.3 m. The mean range of tides at this station is 1.09 m (NOAA Tides and Currents: [http://tidesandcurrents.noaa.gov/station\\_info.shtml?stn=9412110](http://tidesandcurrents.noaa.gov/station_info.shtml?stn=9412110)). Time series of wave amplitudes from this station for a number of historical tsunami events are available for model validation. In 1972, the tide gauge was moved from the neighboring Avila Beach Pier ( $35.17458^{\circ}\text{N}$ ,  $120.73437^{\circ}\text{W}$ ) to its current location, where it is less prone to damage. There are tide gauge data for a small number of tsunamis measured at the Avila Beach Pier location, but none of them has been digitized yet. To validate the models for these events, we employ the maximum water surface elevations obtained from the NGDC tsunami runup database (<http://www.ngdc.noaa.gov/nndc/struts/form?t=101650&s=167&d=166>).

## 4 Model Setup

Specific details of both reference and forecast model grids are provided in Table 1. Bathymetry and extents of these grids are plotted in Figures 6 and 7, respectively. Input parameters for the numerical models are presented in Appendix A. The two models have the same domain coverages but different resolutions in respective grids. The A grids in both models cover the coast of the United States and Mexico from just south of Cape Mendocino on the north to a third of the way down the Baja Peninsula on the south. This grid extent was designed to include San Francisco and Monterrey Bay to the north of Port San Luis and the Southern California Bight to the south. Offshore, the A grids extend past the continental shelf and slope to the Pacific Ocean with depths greater than 4,000 m. The B grids cover the smaller region around Port San Luis, including Morro Bay to the north and the Vandenberg Air Force Base area to the south. The C grids focus on Port San Luis, San Luis Obispo Bay, and

the coast to the northwest (including the Diablo Canyon nuclear power plant location). The forecast model C grid has a resolution of 2 arc sec, or approximately 62 m. The resolution of C grid in the reference model is 0.33 arc sec, or approximately 10 m.

During the initial tests, high-frequency instability has been observed near the coast in C grids, especially around the Point San Luis breakwater and offshore of the Shell Beach community. A 5-point Hanning filter has been applied to the bathymetry and topography in these grids to resolve this instability. Another issue is that the breakwater is so slim that when the DEM was downsampled to compose the lower-resolution forecast model C grid, it did not result in a continuous structure. This issue was resolved by hand-editing the bathymetry of the grid, adding land points to the gaps and the offshore side of the breakwater. This modification is important because the breakwater plays a role in limiting water flows into and out of the bay.

## 5 Results and Discussion

The present forecast and reference models are first tested with historical tsunami events. The objective is to compare the fast-running forecast model with the higher-resolution reference model to check that important details and dynamic characteristics are not lost in the downsampling process when we developed the forecast model grids. For events with available tide gauge data, these data are also compared with the model results. Furthermore, a set of synthetic mega-tsunami events are employed to check that the forecast model is stable under extremely strong forcing conditions. These events are “synthetic” in the sense that they do not represent tsunamis that have happened, but can be viewed as possible worse-case scenarios.

### 5.1 Model validation

The Port San Luis forecast and reference models were tested with 13 historical tsunamis. The locations, magnitudes, and unit source combinations used to describe these events are presented in Table 2. These events range from small to large originating earthquakes (Mw 7.7 to 9.2) and are from various locations around the Pacific Rim. The majority of these events are more recent, since we have higher quality descriptions of the earthquakes, which enable the estimate of tsunamigenic responses with better accuracy. The locations and magnitudes of these historical events are plotted in Figure 8.

Results from the forecast and reference models are compared in Figures 9–21. In each figure, the top two panels show the maximum water surface elevations in the C grids of the forecast and reference models, respectively. The lower panel shows the time series of wave amplitudes from both models at the Port San Luis tide gauge location. In some events, available tide gauge measurements are also plotted and compared with model results. Note that the color scale and axes limits change from figure to figure.

The first event presented here is the 1946 Unimak tsunami due to a Mw 8.5 earthquake (Figure 9). Both the forecast and reference models predict maximum waves of over 2 m at the coast, but minimal flooding. The patterns of maximum water surface elevations are well matched between the two models. In the lower panel, the two models also agree with each other. There are no digitized tide gauge data available for this event. The NGDC tsunami

runup database reports a maximum value of 1.4 m at the Avila Beach tide gauge, while the forecast model predicts a maxima of 2 m at this location.

The 1960 Chile event (Figure 10) results in 2-m waves in San Luis Obispo Bay. There is, again, minimal flooding seen at the creek mouths in Avila Beach, Pismo Beach, and Grover Beach. The wave periods in Port San Luis are distinctive for this event: most incoming waves have frequencies of over an hour. Comparison in this event indicates that the forecast model well matches the higher-resolution reference model in both maximum water surface elevations in the entire C-grid domain and time series of wave amplitudes at the tide gauge location.

Figure 11 shows the model response to the 1964 Alaskan earthquake, which has caused deaths and damage in Alaska, Oregon, and California. Both models show maximum wave amplitudes reach 4 m in the San Luis Obispo Bay and south of Grover Beach. There is flooding in Avila Beach on the low land along Avila Creek and Pismo Creek. Wave amplitude at the Hanford Pier tide gauge location reaches 5 m. At the Avila Beach tide gauge, the forecast model predicted a maximum water surface elevation of 3.9 m, which is much higher than the 1.73 m reported by the NGDC runup database. This disparity could be partly explained by the frequency response of stilling well-type tide gauges (Satake et al., 1988).

The 1994 Kuril event (Figure 12) and 1996 Andreanof event (Figure 13) are both smaller events, but are the first two events where the time series of measured wave amplitudes are available in Port San Luis. Comparison of these data with those simulated by the forecast and reference models indicates that the models do a very good job in predicting the wave amplitudes and wave phases.

Model responses to the 2003 Rat Island and the 2007 Solomon events are presented in Figures 14 and 18, respectively. Both events resulted in small waves in Port San Luis with maximum wave amplitudes on the order of 10 cm. For both events, the forecast and reference models agree well with each other. Tide gauge data are available for the 2007 Solomon tsunami, but the signal is weak and the matching wave peak seen in the time series plot may not be significant.

The 2006 Tonga, 2006 Kuril, 2007 Kuril, and 2009 Samoa tsunamis (Figures 15–17 and 19) are all moderate events with tide gauge data available for model validation. In all these cases, the time series show that the models work very well at predicting the arrival times, phases of the leading waves, and the envelope of wave height maxima. Close inspection shows that the waves predicted by the models have shorter periods. This can be seen clearly in Figure 16 for the 2006 Kuril tsunami, where the arrival of the initial wave is predicted accurately, but by the sixth wave peak, the simulations lead the tide gauge record by nearly 15 min. A possible reason may be that the wave periods are controlled by the natural frequency of the San Luis Obispo Bay, while the bay in the models has a slightly different natural mode.

The last two historical events are both larger events that caused extensive damage in the near field and strong waves in the entire Pacific Ocean. Figure 20 shows the model results for the 2010 Chile tsunami. The two models agree with each other in wave height maxima, with the highest waves cresting 0.6 m in the northern edges of San Luis Bay and offshore of Pismo Beach. No significant flooding is predicted. The recent 2011 Tohoku tsunami (Figure 21) results in almost 3-m waves in San Luis Obispo Bay and slight flooding along the creeks.

Time series at the tide gauge shows that the models provide a very accurate prediction for the initial packet of waves, with both the reference and forecast models closely tracking the tide gauge data.

## 5.2 Stability testing with synthetic scenarios

The forecast and reference models were observed to maintain stability in all simulations of the historical events. To further test the stability of the forecast model, we employ a set of 21 synthetic tsunamis. Among them, 19 are due to Mw 9.3 earthquakes, each of which involves a set of 20 unit sources, corresponding to a rupture area of 1,000 km by 100 km, and are located all around the Pacific Basin. Detailed description of unit sources can be found in Appendix B. For comparison, the 2004 Indian Ocean tsunami that resulted in thousands of deaths in Indonesia and was detectable globally, was the result of a Mw 9.1 earthquake. We also tested the model using a medium and a micro event, to make sure the model triggers correctly for low energy events. Table 3 describes the unit source combinations of the synthetic events, and Figure 22 shows the epicenters of triggering earthquakes. The resulting maximum water surface elevations in the C grid and time series of wave amplitude at the Port San Luis tide gauge location as predicted by the forecast model are shown in Figures 23–43.

The largest response in Port San Luis is due to scenario MOSZ 01-10 of Mw 9.3 earthquake (Figure 38). The forecast model predicts wave amplitudes of over 9 m in San Luis Obispo Bay and significant flooding. The beach front and the creek-side areas of Avila Beach are inundated and some of the town structures are flooded. More significant inundation is seen to the south, where large portions of the Pismo Beach and Grover Beach communities are flooded. Time series of wave amplitude shows a maximum of 8 m and periods of approximately 1 hr between the leading wave peaks. A tsunami of this magnitude would undoubtedly cause extensive damage. However, since it originates on the other side of the Pacific Ocean, hopefully the warning system in place would help local agencies evacuate the communities and save numerous lives.

In the other synthetic cases, significant waves and some inundations are predicted. In general, the largest waves result from the mega events in the Southern Pacific, particularly the already mentioned MOSZ 01-10 event from the Manus-Oceanic Convergent Boundary Subduction Zone and the NTSZ 30-39 event from the New Zealand-Kermadec-Tonga Subduction Zone. Events originating from the Kamchatka-Kuril-Japan-Izu-Mariana-Yap Subduction Zone (KISZ) on the northwestern boundary of the Pacific cause wave amplitudes on the order of 4-8 m in Port San Luis, depending on the orientation of the fault. The Aleutian-Alaska-Cascaadia (ACSZ) and the Central and South America (CSSZ) Subduction Zones result in wave maxima of 1-3 m. It is interesting to point out that of the CSSZ sources, the largest response in Port San Luis is to the tsunami originating the farthest away, due to the fault orientation and the direction along which wave energy is focused. Lastly, the medium and micro synthetic events (Figures 42 and 43) show minimal and negligible response in Port San Luis. These tests indicate that the forecast model will be correctly triggered by events with very low energy.

## 6 Summary and Conclusions

We have developed a tsunami forecast model for Port San Luis, California, and the communities of San Luis Obispo Bay. This area is covered by a grid at a resolution of 2.0 arc sec, equivalent to approximately 62 m. A higher-resolution reference model was also developed in parallel. The forecast model has been validated against historical events and stress-tested using synthetic mega-tsunami scenarios. Reasonable agreement was observed between the forecast and reference models in the historical events. Both models give accurate predictions of wave arrival times and wave heights in response to tsunamis. The forecast model maintained stability in all the computations. All the computations were conducted on a Dell PowerEdge R510 Linux machine,  $2 \times 2.93$  GHz Xeon E5670 hex-core processors. For a 4-hr simulation of wave process, the forecast model requires approximately 11.2 min of CPU time, which is slightly more than the 10-min runtime requirement but the model is still considered fast enough. This model is ready to be integrated into SIFT for real-time operational forecasts.

## Acknowledgement

This report was first draft by Dylan Righi. The authors wish to thank Yong Wei, Burak Uslu, and Diego Arcas for guidance and assistance with model development and troubleshooting, Lijuan Tang for providing source information for two of the historical events, Edison Gica and Michael Spillane for helpful document feedback and the team of Marie Eble, Katherine Burgess, Lindsey Wright, Sandra Bigley, and James Anderson for editorial, review, and management.

Funding for this publication and all works leading to the development of a tsunami forecast model for Port San Luis was provided by NOAA. This publication was partially funded by the Joint Institute for the Study of the Atmosphere and Ocean (JISAO) under NOAA Cooperative Agreement No. NA10OAR4320148 and NA08OAR4320899, JISAO Contribution No. 2443. This is PMEL Contribution No. 3360.

## C Forecast Model Testing

Authors: Nazila Merati, Yong Wei, and Jean Newman

### C.1 Purpose

Forecast models are tested with synthetic tsunami events covering a range of tsunami source locations. Testing is also done with selected historical tsunami events when available.

The purpose of forecast model testing is three-fold. The first objective is to assure that the results obtained with NOAA's tsunami forecast system, which has been released to the Tsunami Warning Centers for operational use, are identical to those obtained by the researcher during the development of the forecast model. The second objective is to test the forecast model for consistency, accuracy, time efficiency, and quality of results over a range of possible tsunami locations and magnitudes. The third objective is to identify bugs and issues in need of resolution by the researcher who developed the Forecast Model or by the forecast software development team before the next version release to NOAA's two tsunami warning centers.

Local hardware and software applications, and tools familiar to the researcher(s), are used to run the Method of Splitting Tsunamis (MOST) model during the forecast model development. The test results presented in this report lend confidence that the model performs as developed and produces the same results when initiated within the forecast application in an operational setting as those produced by the researcher during the forecast model development. The test results assure those who rely on the Adak tsunami forecast model that consistent results are produced irrespective of system.

### C.2 Testing Procedure

The general procedure for forecast model testing is to run a set of synthetic tsunami scenarios and a selected set of historical tsunami events through the forecast system application and compare the results with those obtained by the researcher during the forecast model development and presented in the Tsunami Forecast Model Report. Specific steps taken to test the model include:

1. Identification of testing scenarios, including the standard set of synthetic events, appropriate historical events, and customized synthetic scenarios that may have been used by the researcher(s) in developing the forecast model.
2. Creation of new events to represent customized synthetic scenarios used by the researcher(s) in developing the forecast model, if any.
3. Submission of test model runs with the forecast system, and export of the results from A, B, and C grids, along with time series.
4. Recording applicable metadata, including the specific version of the forecast system used for testing.
5. Examination of forecast model results from the forecast system for instabilities in both time series and plot results.

6. Comparison of forecast model results obtained through the forecast system with those obtained during the forecast model development.
7. Summarization of results with specific mention of quality, consistency, and time efficiency.
8. Reporting of issues identified to modeler and forecast software development team.
9. Retesting the forecast models in the forecast system when reported issues have been addressed or explained.

Synthetic model runs were tested on a DELL PowerEdge R510 computer equipped with two Xeon E5670 processors at 2.93 Ghz, each with 12 MBytes of cache and 32GB memory. The processors are hex core and support hyper threading, resulting in the computer performing as a 24 processor core machine. Additionally, the testing computer supports 10 Gigabit Ethernet for fast network connections. This computer configuration is similar or the same as the configurations of the computers installed at the Tsunami Warning Centers so the compute times should only vary slightly.

### C.3 Results

The Port San Luis forecast model was tested with NOAA's tsunami forecast system version 3.2.

The Port San Luis, California, forecast model was tested with four synthetic scenarios and one historical tsunami event. Test results from the forecast system and comparisons with the results obtained during the forecast model development are shown numerically in Table C1 and graphically in Figures C1 to C5. Results show that the minimum and maximum amplitudes and time series generated from SIFT agree with those obtained during the forecast model development. The model run time (wall clock time) was 30 min for 10 hr of simulation time, and 10 min for 4.0 hr of simulation time that satisfies time efficiency requirements.

Four synthetic events were run on the Port San Luis forecast model. The modeled scenarios were stable for all cases tested, with no instabilities or ringing. Results show that the largest modeled height was 915.2 cm and originated in the New Zealand-Kermadec-Tonga (NTSZ 30-39) source. Amplitudes greater than 100 cm were recorded for 4 out of 4 test sources. The smallest signal of 157.2 cm was recorded at the Central and South America (CSSZ 89-98) source. Direct comparisons, of output from the forecast tool with results of both the historical event (2006 Kuril) and available development synthetic events, demonstrated that the wave pattern were similar in shape, pattern, and amplitude.

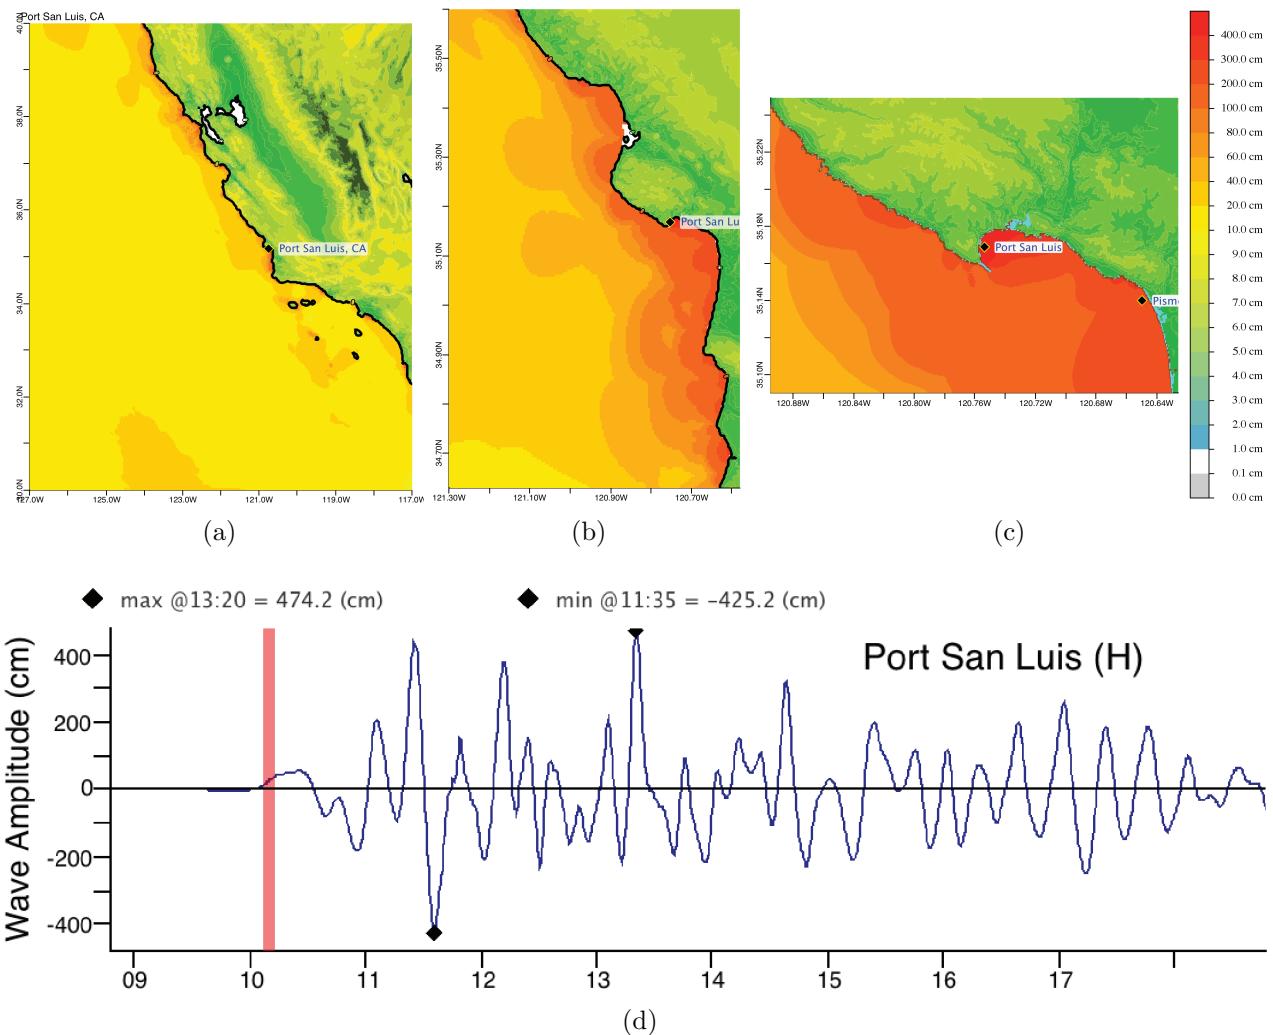

Figure C1: Response of the Port San Luis forecast model to synthetic scenario KISZ 22-31 ( $\alpha=25$  m). Maximum sea surface elevation for (a) A grid, (b) B grid, (c) C grid. Sea surface elevation time series at the C-grid warning point (d).

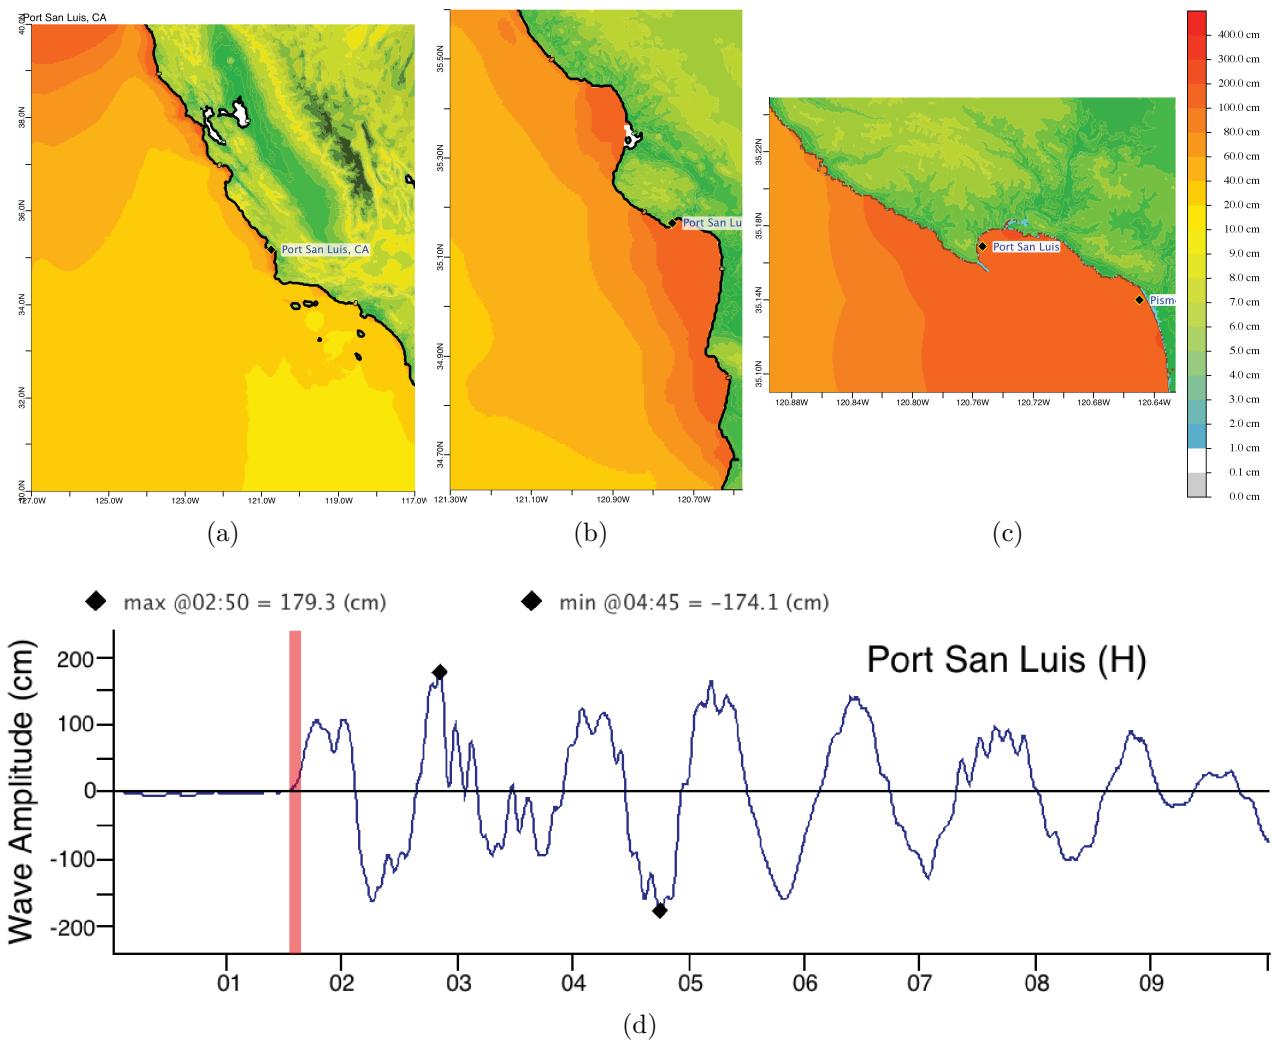

Figure C2: Response of the Port San Luis forecast model to synthetic scenario ACSZ 56-65 ( $\alpha=25$  m). Maximum sea surface elevation for (a) A grid, (b) B grid, (c) C grid. Sea surface elevation time series at the C-grid warning point (d).

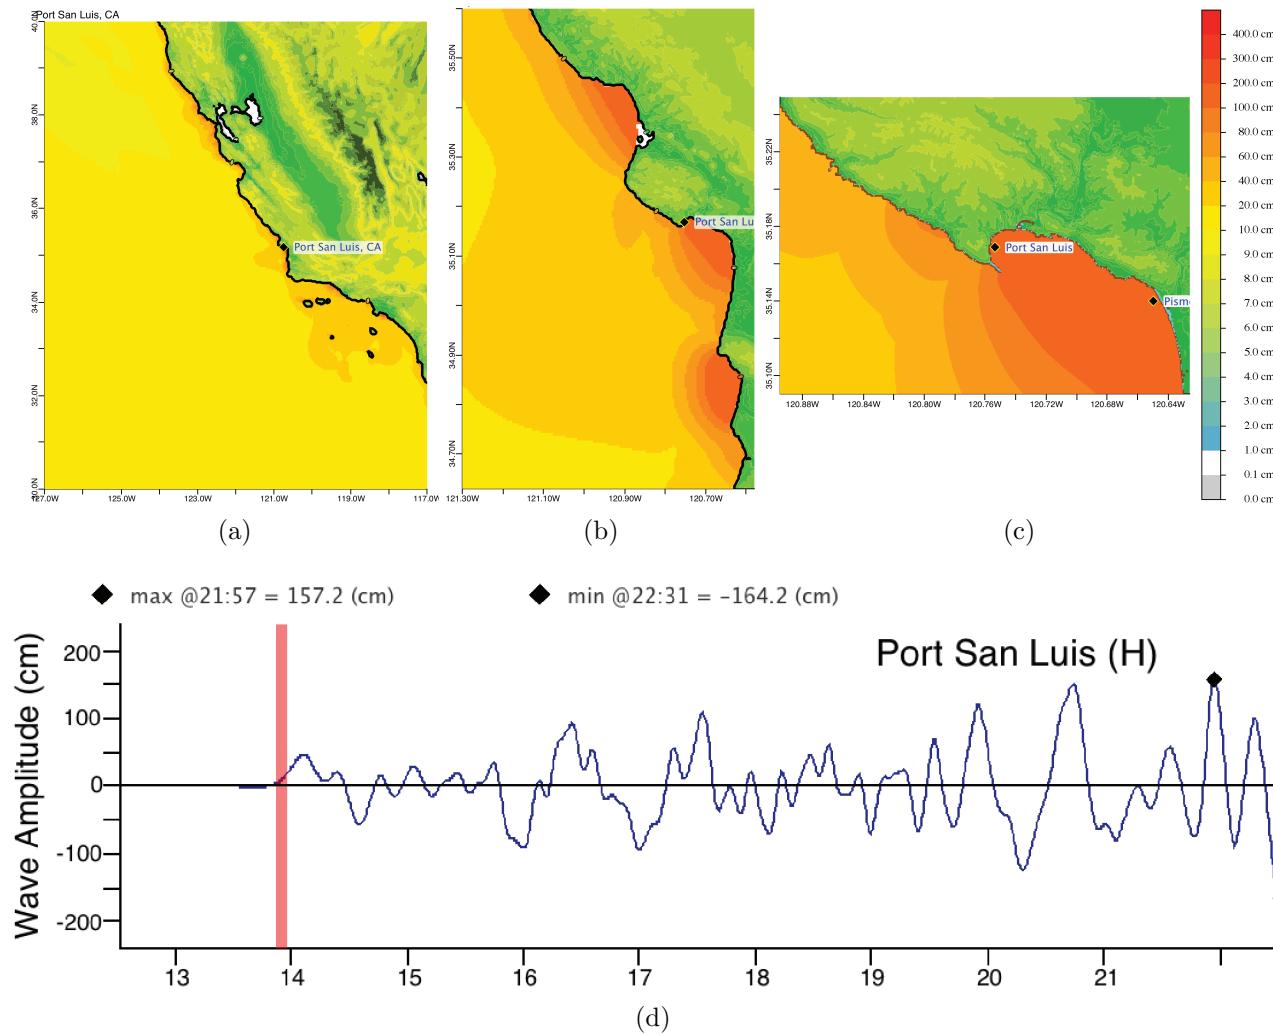

Figure C3: Response of the Port San Luis forecast model to synthetic scenario CSSZ 89-98 ( $\alpha=25$  m). Maximum sea surface elevation for (a) A grid, (b) B grid, (c) C grid. Sea surface elevation time series at the C-grid warning point (d).

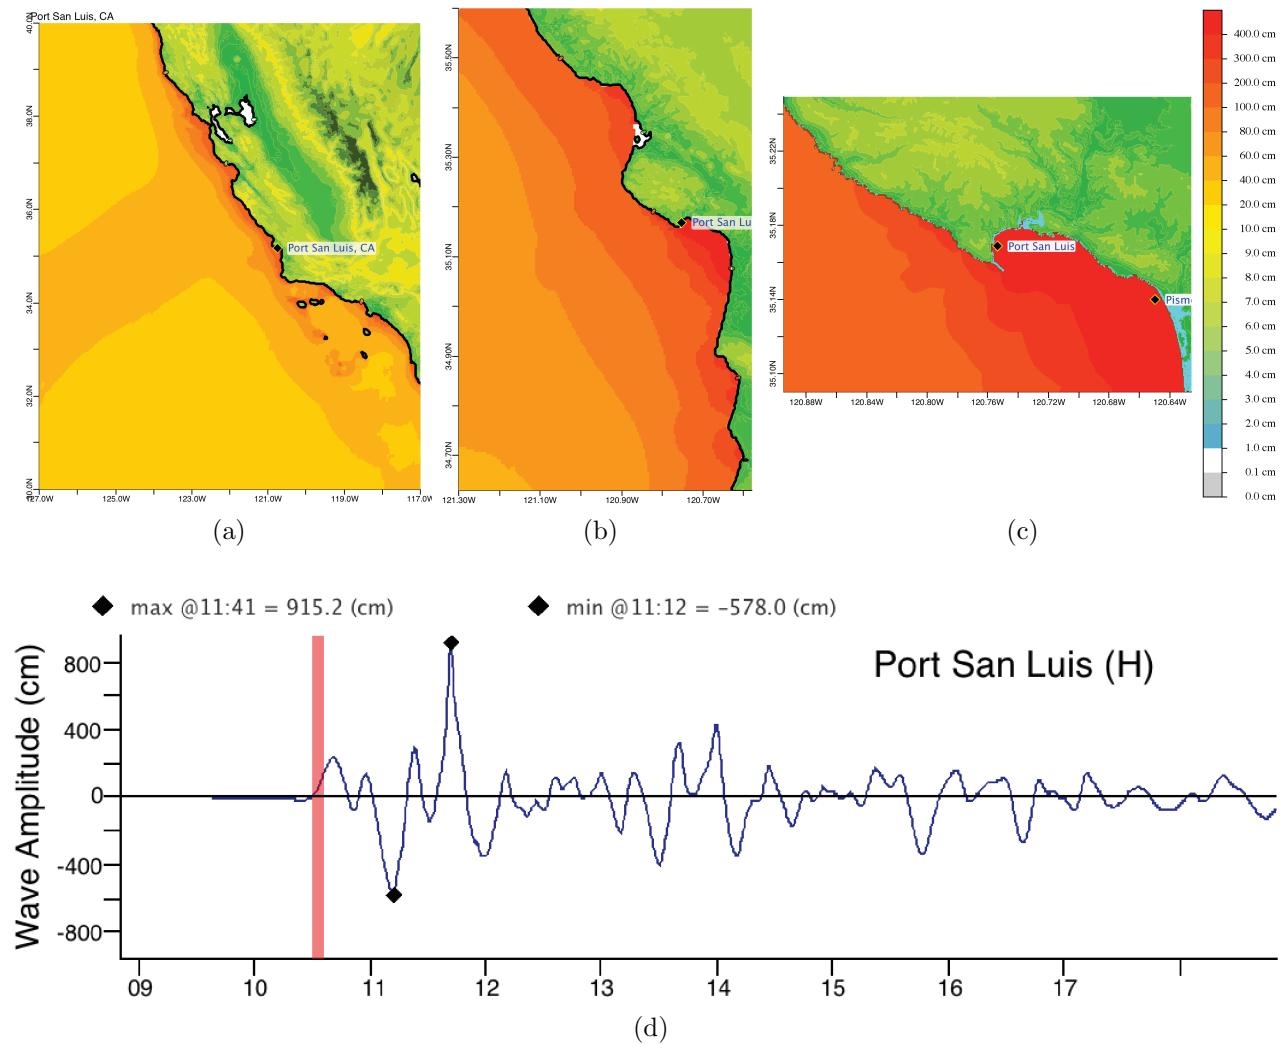

Figure C4: Response of the Port San Luis forecast model to synthetic scenario NTSZ 30-39 ( $\alpha=25$  m). Maximum sea surface elevation for (a) A grid, (b) B grid, (c) C grid. Sea surface elevation time series at the C-grid warning point (d).

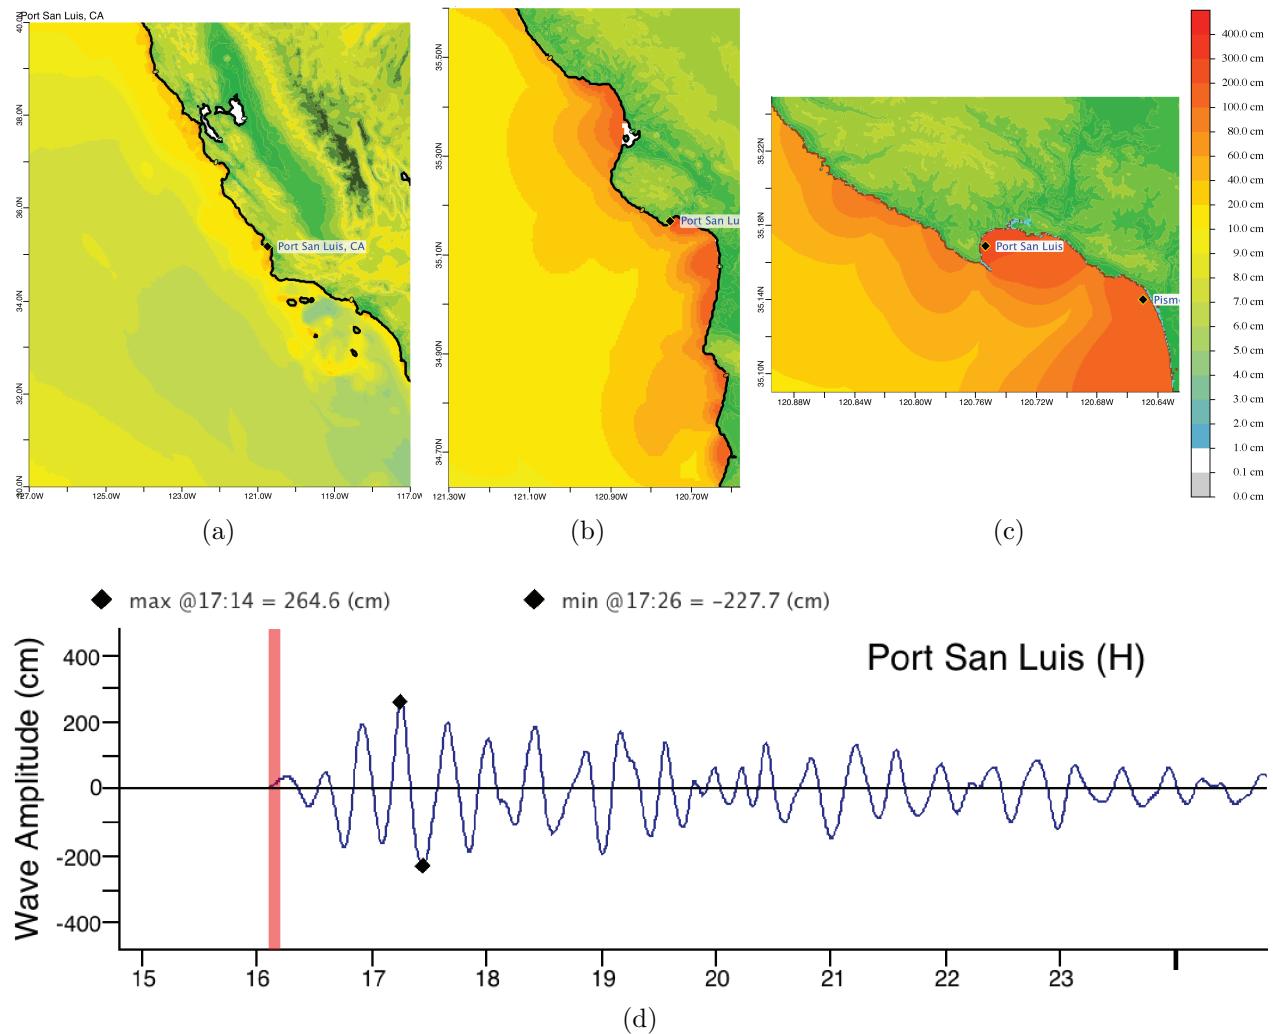

Figure C5: Response of the Port San Luis forecast model to the 2011 Tohoku, Japan tsunami. Maximum sea surface elevation for (a) A grid, (b) B grid, (c) C grid. Sea surface elevation time series at the C-grid warning point (d).

Table C1: Table of maximum and minimum amplitudes (cm) at the Port San Luis, California, warning point for synthetic and historical events tested using SIFT 3.2 and obtained during development.

Scenario Name	Source Zone	Tsunami Source	$\alpha$ [m]	SIFT Max (cm)	Development Max (cm)	SIFT Min (cm)	Development Min (cm)
<b>Mega-tsunami Scenarios</b>							
KISZ 22-31	Kamchatka–Yap–Mariana–Izu–Bonin	A22-A31, B22-B31	25	474.2.4	472.6	-425.2	-425.5
ACSZ 56-65	Aleutian–Alaska–Cascadia	A56-A65, B56-B65	25	179.3	179.6	-174.1	-173.6
CSSZ 89-98	Central and South America	A89-A98, B89-B98	25	157.2	157.2	-164.2	-164.2
NTSZ 30-39	New Zealand–Kermadec–Tonga	A30-A39, B30-B39	25	915.2	916.4	-578.0	-578.1
<b>Historical Events</b>							
2011 Tohoku2011	Kamchatka–Yap–Mariana–Izu–Bonin	$4.66 \times b24 + 12.23 \times b25 + 26.31 \times a26$ $21.27 \times b26 + 22.75 \times a27 + 4.98 \times b27$		264.6	264.6	-227.7	-227.7
